DataFrameIndexingAndLoading_ed

November 7, 2020

In this course, we'll be largely using smaller or moderate-sized datasets. A common workflow is to read the dataset in, usually from some external file, then begin to clean and manipulate the dataset for analysis. In this lecture I'm going to demonstrate how you can load data from a comma separated file into a DataFrame.

```
[1]: # Lets just jump right in and talk about comma separated values (csv) files.
    → You've undoubtedly used these -
    # any spreadsheet software like excel or google sheets can save output in CSV_{f \sqcup}
    →format. It's pretty loose as a
    # format, and incredibly lightweight. And totally ubiquitous.
    # Now, I'm going to make a quick aside because it's convenient here. The \Box
    → Jupyter notebooks use ipython as the
    # kernel underneath, which provides convenient ways to integrate lower level
    ⇒shell commands, which are
    # programs run in the underlying operating system. If you're not familiar with
    → the shell don't worry too much
    # about this, but if you are, this is super handy for integration of your data_
    →science workflows. I want to
    # use one shell command here called "cat", for "concatenate", which just _{\sqcup}
    →outputs the contents of a file. In
    # ipython\ if\ we\ prepend\ the\ line\ with\ an\ exclamation\ mark\ it\ will\ execute\ the
    →remainder of the line as a shell
    # command. So lets look at the content of a CSV file
    !cat datasets/Admission_Predict.csv
```

```
[2]: # We see from the output that there is a list of columns, and the column
    →identifiers are listed as strings on
    # the first line of the file. Then we have rows of data, all columns separated _{f L}
    →by commas. Now, there are lots
    ⇒specification. So you should be
    # prepared to do a bit of work when you pull down CSV files to explore. But \Box
    → this lecture isn't focused on CSV
    # files, and is more about pandas DataFrames. So lets jump into that.
   # Let's bring in pandas to work with
   import pandas as pd
    # Pandas mades it easy to turn a CSV into a dataframe, we just call read csv()
   df = pd.read_csv('datasets/Admission_Predict.csv')
    # And let's look at the first few rows
   df.head()

[7]: \# So that works well, but it's a bit fragile. What if that was a tab instead of \sqcup
    →a space? Or two spaces?
    # Another way is to create some function that does the cleaning and then tell_{\mathsf{L}}
    →renamed to apply that function
    # across all of the data. Python comes with a handy string function to strip_{\sqcup}
    →white space called "strip()".
    # When we pass this in to rename we pass the function as the mapper parameter, \Box
    →and then indicate whether the
    # axis should be columns or index (row labels)
```

```
# Let's take a look at results
    new_df.head()

[8]: # Now we've got it - both SOP and LOR have been renamed and Chance of Admit has \Box
    →been trimmed up. Remember
    # though that the rename function isn't modifying the dataframe. In this case, \Box
    \rightarrowdf is the same as it always
    # was, there's just a copy in new_df with the changed names.
    df.columns
[8]: Index(['GRE Score', 'TOEFL Score', 'University Rating', 'SOP', 'LOR ', 'CGPA',
           'Research', 'Chance of Admit'],
          dtype='object')
[9]: # We can also use the df.columns attribute by assigning to it a list of column
    →names which will directly
    # rename the columns. This will directly modify the original dataframe and is \Box
     →very efficient especially when
    # you have a lot of columns and you only want to change a few. This technique
    →is also not affected by subtle
    # errors in the column names, a problem that we just encountered. With a list, \Box
    →you can use the list index to
    # change a certain value or use list comprehension to change all of the values
    # As an example, lets change all of the column names to lower case. First well
    \rightarrowneed to get our list
    cols = list(df.columns)
    # Then a little list comprehenshion
    cols = [x.lower().strip() for x in cols]
    # Then we just overwrite what is already in the .columns attribute
    df.columns=cols
```

new_df=new_df.rename(mapper=str.strip, axis='columns')

```
# And take a look at our results
df.head()
```

In this lecture, you've learned how to import a CSV file into a pandas DataFrame object, and how to do some basic data cleaning to the column names. The CSV file import mechanisms in pandas have lots of different options, and you really need to learn these in order to be proficient at data manipulation. Once you have set up the format and shape of a DataFrame, you have a solid start to further actions such as conducting data analysis and modeling.

Now, there are other data sources you can load directly into dataframes as well, including HTML web pages, databases, and other file formats. But the CSV is by far the most common data format you'll run into, and an important one to know how to manipulate in pandas.
